Fluent Backend Tutorials

Create a Hummingbird + Flu... ∨

ntroduction

Build a Galaxy Backend

Create a Hummingbird + Fluent application.

Create a simple web application using the Hummingbird template.

15mins

Estimated Time

Section 1

Create your project

Clone the Hummingbird template, configure a project and review the contents of the generated project.

Clone template

No Preview ∠

1 > git clone https://github.com/hummingbird-project/template

Step 1

Clone the Hummingbird template GitHub project

Step 2

Create your project, using the template configure script. Press return on each question to use the default value.

Step 3

Add the hummingbird-fluent and fluent-sqlite-driver dependencies.

Like with Vapor, you can use different Fluent Drivers as your backing storage.

Section 2

Add Fluent

With your Package.swift set up, lets add Fluent to your project.

Open Sources/App/Application+build .swift.

```
Sources/App/Application+build.swift
1 import Hummingbird
```

import Logging

import FluentSQLiteDriver

import Foundation

import HummingbirdFluent

/// Application arguments protocol. We use a protocol so we can call

/// `buildApplication` inside Tests as well as in the App executable.

/// Any variables added here also have to be added to `App` in App.swift

Add the Fluent dependencies, and modify the AppArguments to contain two new variables.

Step 2

Open Sources/App/App.swift

This contains an App type conforming to AsyncParsableCommand with three options, the hostname and port are used to define the server bind address, logLevel sets the level of logging required. Finally the run() function which calls buildApplication(_:) to create an Application and then runs it using runService(). You can find out more about the argument parser library <a href="https://example.com/here/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/bases/base

Step 3

Add the new app arguments with default values.

Step 4

Open Sources/App/Application+build .swift again.

We can now add Fluent to our application's lifecycle.

Step 5

First, create a Fluent object and add the SQLite driver to Fluent.

Depending on the inMemoryDatabase boolean, this application can run completely inmemory. This is useful for testing, as it loses all data when the application is re-launched.

```
/// `TestArguments` in AppTest.swift
    public protocol AppArguments {
12
        var inMemoryDatabase: Bool { get }
13
        var migrate: Bool { get }
14
        var hostname: String { get }
        var port: Int { get }
15
16
        var logLevel: Logger.Level? { get }
17
    }
18
19
    // Request context used by application
20
    typealias AppRequestContext = BasicRequestContext
21
22
    /// Build application
23
    /// - Parameter arguments: application arguments
    public func buildApplication(_ arguments: some AppArguments) async throw
24
25
        let environment = Environment()
26
        let logger = {
27
             var logger = Logger(label: "TodosFluent")
28
             logger.logLevel =
29
             arguments.logLevel ??
30
             environment.get("LOG_LEVEL").flatMap { Logger.Level(rawValue: $0
31
                 .info
32
             return logger
33
        }()
34
        let router = buildRouter()
        let app = Application(
35
36
             router: router,
37
             configuration: .init(
38
                 address: .hostname(arguments.hostname, port: arguments.port)
                 serverName: "TodosFluent"
39
40
             ),
41
             logger: logger
42
43
        return app
    }
44
45
46
    /// Build router
47
    func buildRouter() -> Router<AppRequestContext> {
48
        let router = Router(context: AppRequestContext.self)
49
        // Add middleware
        router.addMiddleware {
50
51
             // logging middleware
52
             LogRequestsMiddleware(.info)
53
        }
54
        // Add default endpoint
```

Next, we'll use Fluent as a persistence mechanism for the Persist framework. This step is **optional** for this tutorial.

This allows it to integrate with Hummingbird's ecosystem, including the Auth framework.

Step 7

Finally, both Fluent and the FluentPersistDriver are added to swift-service-lifecycle.

Section 3

Add Galaxy API

Add your database models and routes to edit them.

```
Sten 1
```

Create a file named Galaxy.swift, and add the following Fluent Model.

This Fluent model has the 'id' and a 'name' properties.

```
Sources/App/Galaxy.swift
                                                              No Preview ∠
   import FluentKit
    import Foundation
    import Hummingbird
    final class Galaxy: Model, @unchecked Sendable, ResponseCodable {
 6
        // Name of the table or collection.
7
        static let schema = "galaxies"
 8
9
        // Unique identifier for this Galaxy.
10
        @ID(key: .id)
        var id: UUID?
11
12
13
        // The Galaxy's name.
        @Field(key: "name")
```

Before being able to use a Model, a migration must be added.

A migration creates or reverts a diff to the schema in the database.

Step 3

Open Sources/App/Application+build swift again. Fluent is now a completely blank slate, let's set it up.

The newly added migrations are added to Fluent. Make sure that any new migrations are added to Fluent in the right order.

Step 4

The final step to set up Fluent is to run the migrations.

It's common to explicitly run migrations, but for small scale set-ups can also run migrations on every app launch.

Step 5

If we look further down the file we can find the buildRouter() function.

Here we create the Router. We add a logging middleware to it (this logs all requests to the router). The function uses a result builder to create a stack of middleware, but you can also use Router.add(middleware:) to add individual middleware. Finally we add a single endpoint GET / which returns "Hello!"

```
15
        var name: String
16
17
        // Creates a new, empty Galaxy.
18
        init() { }
19
20
        // Creates a new Galaxy with all properties set.
21
        init(id: UUID? = nil, name: String) {
22
            self.id = id
23
            self.name = name
        }
24
25
    }
```

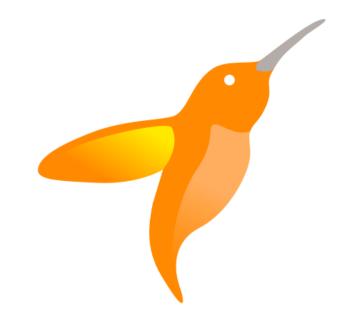

We'll add a single route GET /galaxies, which lists all registered galaxies.

Because the database is empty now, we'll add a route PUT /galaxies to add your own galaxies.

Section 4

Test your Backend

Now that your Fluent backend is complete, it's time to validate the results!

Step 1

We can run the application and use curl to test it works.

First, create your own galaxy!

Step 2

Then, query the list of galaxies.

Test Application

No Preview ∠

- 1 > curl -i -X PUT -H "Content-Type: application/json" -d '{"name":"Androme
- 2 HTTP/1.1 201 Created
- 3 Content-Length: 0
- 4 Date: Sat, 23 Nov 2024 09:22:26 GMT
- 5 Server: TodosFluent

You can see the galaxy added in the first call, is returned when we ask to list all the galaxies.
